# Data Analysis Report: Weather Data Set

Objective: This report presents the findings of our analysis of weather within our subscription-based service. The goal is to identify key factors contributing to weather and provide actionable recommendations to mitigate it

# Import the Required Library:

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
```

The importing of libraries will help data analysts to do analysis on the datasets and get insights about the data.

## **Load the CSV File:**

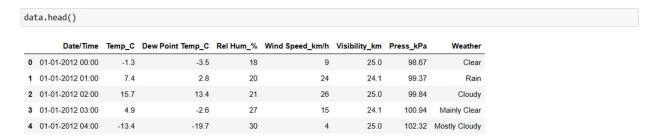

Use the **read\_csv** function to load the CSV file into a Data Frame. Provide the path or URL of the CSV file as an argument to the function.

```
data=pd.read_csv(r'C:\Users\priya\Downloads\data set with questions\data set with questions\Weather Data.csv')
```

This line of code reads the CSV file named 'Weather data.csv' and stores its contents in the Data Frame 'data'.

## **Exploring the data:**

Once loaded the data into Data Frame, you can start exploring it. Common DataFrame operations include:

data.head(): Displays the first 5 rows of the DataFrame to get a quick look at the data.

```
data.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 8784 entries, 0 to 8783
Data columns (total 8 columns):
                       Non-Null Count
 #

data.describe(): Provide summary statistics for numeric columns.

data.columns(): List the column names.

## **Analysis Methods:**

1. Find all the unique 'Wind Speed' values in the data

There are 34 unique wind speed values in the data

**data['Wind Speed\_km/h']:** This part of the code selects the 'Wind Speed\_km/h' column from the DataFrame 'data'. It accesses the data in the specific column.

**.nunique()**: This is a Pandas function that operates on a Series (a single column of data) and calculates the number of unique values in that Series. In this case, it calculates the number of unique wind speed values in the 'Wind Speed km/h' column.

So, when you execute data['Wind Speed\_km/h'].nunique(), it will return an integer value representing the count of unique wind speed values in the specified column. This can be useful to understand the diversity of wind speeds in the dataset and get a sense of the variability in the 'Wind Speed\_km/h' data.

**.unique():** This is a Pandas function that operates on a Series (a single column of data) and returns an array containing all the unique values found in that Series. In this case, it retrieves an array of unique wind speed values from the 'Wind Speed\_km/h' column.

So, when you execute **data['Wind Speed\_km/h'].unique()**, you will get an array of all the distinct wind speed values present in the specified column. This can be useful for various purposes, such as identifying the range of wind speeds in your dataset, checking for anomalies or outliers, or creating a list of unique wind speeds for further analysis or visualization.

# 2. Find the number of times when the 'Weather is exactly Clear'.

```
data.loc[data['Weather']=='Clear','Weather'].value_counts()
Clear 1326
Name: Weather, dtype: int64
```

#### 1326 times the weather is exactly clear

**data.loc[]:** The .loc function is used to locate rows in the DataFrame based on a specified condition. In this case, it's used to select rows where the 'Weather' column is equal to 'Clear'.

**.value\_counts():** This is a Pandas function that operates on a Series and counts the number of occurrences of each unique value in the Series. In this case, it counts how many times 'Clear' appears in the 'Weather' column after filtering for rows with 'Clear' weather conditions.

data.loc[data['Weather'] == 'Clear', 'Weather'].value\_counts(): It will get a count of how many times the weather condition 'Clear' appears in the 'Weather' column of the DataFrame 'data.' This can be useful for understanding how frequently clear weather occurs in the dataset or for summarizing the frequency of specific categories within a categorical variable like 'Weather'.

# 3. Find the number of times when the 'Wind Speed was exactly 4 km/h'.

```
data.loc[data['Wind Speed_km/h']==4,'Wind Speed_km/h'].value_counts()
4     474
Name: Wind Speed_km/h, dtype: int64
```

#### 474 times the wind speed was exactly 4 km/h

data.loc[data['Wind Speed\_km/h']==4, 'Wind Speed\_km/h']: This part of the code selects the subset of the DataFrame 'data' where the 'Wind Speed\_km/h' column contains the value 4. It specifically selects the 'Wind Speed\_km/h' column for these rows.

So, when data.loc[data['Wind Speed\_km/h']==4,'Wind Speed\_km/h'].value\_counts(), is executed, will get a count of how many times the wind speed is 4 km/h in the 'Wind Speed\_km/h' column of the DataFrame 'data.' This can be useful for understanding how frequently wind speeds of 4 km/h occur in the dataset or for summarizing the frequency of specific values within a numeric variable like 'Wind Speed\_km/h'.

#### 4. Find out all the Null Values in the data.

```
data.isnull().sum()
Date/Time
                     0
Temp_C
                     0
Dew Point Temp C
                     0
Rel Hum %
Wind Speed km/h
                     0
Visibility km
                     0
Press kPa
                     0
Weather
                     0
dtype: int64
```

This data set is having **ZERO** null values

**data.isnull():** This part of the code creates a new DataFrame that has the same shape as 'data' but contains Boolean values (True or False) for each cell. Each element in this new DataFrame is True if the corresponding cell in 'data' is a missing value and False if it is not.

**.sum():** The. sum() function is then applied to this Boolean DataFrame. When you apply. sum() to a DataFrame of Booleans, it calculates the sum of True values along each column. Since True is treated as 1 and False as 0 when you sum them up, this effectively counts the number of True values in each column, which corresponds to the number of missing values.

So, when you execute **data.isnull().sum()**, you will get a Series that shows the count of missing values for each column in the DataFrame 'data.' This can be useful for identifying which columns have missing data and for assessing the extent of missingness in your dataset.

#### 5. Rename the column name 'Weather' of the dataframe to 'Weather Condition'.

```
dc=data.rename(columns={'Weather': 'Weather Condition'})

dc.columns

Index(['Date/Time', 'Temp_C', 'Dew Point Temp_C', 'Rel Hum_%',
    'Wind Speed_km/h', 'Visibility_km', 'Press_kPa', 'Weather Condition'],
    dtype='object')
```

Changed column name from Weather-to-Weather Condition

.rename(columns={'Weather': 'Weather Condition'}): This is a Pandas function that allows you to rename the columns of a DataFrame. In this case:

**columns** = {'Weather': 'Weather Condition'} is a dictionary where the key 'Weather' represents the current column name that you want to change, and the value 'Weather Condition' represents the new column name you want to assign.

#### 6. What is the mean 'Visibility'?

```
data['Visibility_km'].mean()
27.664446721311478
```

The mean of the visibility is 27.664446721311478

The code data['Visibility\_km'].mean() is used to calculate the mean (average) value of the 'Visibility\_km' column in a DataFrame called 'data'.

#### 7. What is the Standard Deviation of 'Pressure' in this data?

```
data['Press_kPa'].std()
0.8440047459486459
```

The standard deviation of pressure is 0.8440047459486459

The code data['Press\_kPa'].std() is used to calculate the standard deviation value of the 'Press kPa' column in the DataFrame called 'data'.

### 8. What is the Variance of 'Relative Humidity' in this data?

```
data['Rel Hum_%'].var()
286.2485501985015
```

The **Variance** of pressure is **286.2485501985015** 

The code data['Rel Hum\_%'].var() is used to calculate the variance value of the 'Rel Hum\_%' column in the DataFrame called 'data'.

#### 9. Find all instances when 'Snow' was recorded.

| <pre>data.loc[data['Weather']=='Snow',['Date/Time','Weather']]</pre> |  |
|--|--|
|  |  |

|      | Date/Time        | Weather |
|------|------------------|---------|
| 11   | 01-01-2012 11:00 | Snow    |
| 70   | 03-01-2012 22:00 | Snow    |
| 73   | 04-01-2012 01:00 | Snow    |
| 105  | 05-01-2012 09:00 | Snow    |
| 112  | 05-01-2012 16:00 | Snow    |
|      |                  |         |
| 8573 | 9/22/2012 13:00  | Snow    |
| 8650 | 9/25/2012 18:00  | Snow    |
| 8671 | 9/26/2012 15:00  | Snow    |
| 8713 | 9/28/2012 1:00   | Snow    |
| 8734 | 9/28/2012 8:00   | Snow    |

390 rows × 2 columns

Out of 8784 rows there are 390 rows having snow weather

The code data.loc[data['Weather'] == 'Snow', ['Date/Time', 'Weather']] is used to filter and select specific rows and columns from a DataFrame called 'data' based on a condition.

['Date/Time', 'Weather']: Inside the .loc function, you specify the columns you want to select for the rows that meet the condition. In this case, you are selecting the 'Date/Time' and 'Weather' columns.

#### 10. Find all instances when 'Wind Speed is above 24' and 'Visibility is 25'.

| Wind | Speed_km/h | Visibility_km |
|------|------------|---------------|
| 2    | 26         | 25.0          |
| 73   | 35         | 25.0          |
| 126  | 39         | 25.0          |
| 158  | 26         | 25.0          |
| 184  | 44         | 25.0          |
|      |            |               |
| 8707 | 33         | 25.0          |
| 8714 | 26         | 25.0          |
| 8738 | 28         | 25.0          |
| 8745 | 28         | 25.0          |
| 8776 | 43         | 25.0          |

Out of 8784 rows of different data there are 308 rows with wind speed is greater than 24 and visibility is equal to 25.

data.loc[] is used to select rows and columns from a Pandas DataFrame called data.

(data['Wind Speed\_km/h'] > 24) is a Boolean condition that checks whether the values in the 'Wind Speed\_km/h' column of the DataFrame are greater than 24. This condition will create a Boolean Series with True for rows where the wind speed is greater than 24 and False otherwise.

(data['Visibility\_km'] == 25) is another Boolean condition that checks whether the values in the 'Visibility\_km' column of the DataFrame are equal to 25. This condition will create a Boolean Series with True for rows where the visibility is exactly 25 kilometers and False otherwise.

(data['Wind Speed\_km/h'] > 24) & (data['Visibility\_km'] == 25) combines the two conditions using the & operator. This results in a Boolean Series that is True only for rows where both conditions are satisfied, meaning the wind speed is greater than 24 km/h, and the visibility is 25 kilometers.

['Wind Speed\_km/h', 'Visibility\_km'] is a list of column names that you want to select from the DataFrame. In this case, you want to select the 'Wind Speed\_km/h' and 'Visibility\_km' columns for the rows that meet the combined condition.

#### 11. What is the Mean value of each column against each 'Weather Condition?

g=data.groupby('Weather')
g.mean(numeric\_only=True)

|                               | Temp_C    | Dew Point Temp_C | Rel Hum_% | Wind Speed_km/h | Visibility_km | Press_kPa  |
|-------------------------------|-----------|------------------|-----------|-----------------|---------------|------------|
| Weather                       |           |                  |           |                 |               |            |
| Clear                         | 6.825716  | 0.089367         | 67.127451 | 10.557315       | 30.153243     | 101.084495 |
| Cloudy                        | 7.970544  | 2.375810         | 67.349537 | 16.127315       | 26.625752     | 101.056852 |

The following data frame shows the average of each column against each weather condition.

For clear weather condition the average Temperature is 6.825716.

For **cloudy weather** the average temperature is 7.970544. and so on....

**g.mean(numeric\_only=True):** This part of the code calculates the mean (average) for each group within the GroupBy object 'g.'

The **numeric\_only=True** argument is used to ensure that only numeric columns are included in the calculation. If there are non-numeric columns in the DataFrame, they will be excluded from the mean calculation.

The result will be a new DataFrame where the rows correspond to unique values in the 'Weather' column, and the columns represent the mean values of numeric columns for each weather category.

For example, if your original 'data' DataFrame had columns like 'Temperature,' 'Humidity,' and 'Wind\_Speed,' and you used this code to group by 'Weather,' the resulting DataFrame would have rows corresponding to different weather conditions (e.g., 'Sunny,' 'Rainy,' 'Cloudy') and columns representing the mean values of 'Temperature,' 'Humidity,' and 'Wind\_Speed' for each weather condition.

## 12. What is the Minimum & Maximum value of each column against each 'Weather Condition ?

g.min()

The above data frame shows the minimum values of each column against all kind of weather conditions.

The column called weather is grouped by categories and stored to a variable called 'g', and the aggregate function '.min()' is applied to the grouped data. It'll return the minimum value of each column against each weather condition.

The above data frame shows the maximum values of each column against each weather condition.

### 13. Show all the Records where Weather Condition is Fog.

| pd.Da | ataFrame( |
|-------|-----------|
|       | Weather   |
| 13    | Fog       |
| 53    | Fog       |
| 136   | Fog       |
| 197   | Fog       |
| 278   | Fog       |
|       |           |
| 8475  | Fog       |
| 8511  | Fog       |
| 8518  | Fog       |
| 8537  | Fog       |
| 8771  | Fog       |

150 rows × 1 columns

Out of 8784 rows there are 150 rows having foggy weather condition

**data['Weather']:** This part of the code extracts the 'Weather' column from the original DataFrame 'data.' It selects only the 'Weather' column.

**data['Weather']=='Fog':** This part of the code creates a Boolean Series that checks whether each row in the 'Weather' column is equal to the string 'Fog.' It results in a Series of True and False values, indicating which rows have 'Fog' as their weather condition.

**data.loc[...]:** The .loc indexer is used to select rows from the original DataFrame 'data' based on the condition specified inside the square brackets. In this case, it selects rows where the condition data['Weather']=='Fog' is True.

**pd.DataFrame(...):** Finally, the selected rows are wrapped in pd.DataFrame(...), which creates a new DataFrame containing only the rows where the 'Weather' column has the value 'Fog.'

So, the resulting DataFrame will contain all the columns from the original DataFrame ('data') but only include rows where the weather condition is 'Fog.' This essentially filters the original data to include only the rows associated with 'Fog' weather conditions.

#### 14. Find all instances when 'Weather is Clear' or 'Visibility is above 40'.

data.loc[(data['Weather']=='Clear') | (data['Visibility\_km']>40),['Weather','Visibility\_km']]

|      | Weather       | Visibility_km |
|------|---------------|---------------|
| 0    | Clear         | 25.0          |
| 9    | Clear         | 48.3          |
| 16   | Clear         | 25.0          |
| 17   | Mainly Clear  | 48.3          |
| 18   | Cloudy        | 48.3          |
|      | ·             |               |
| 8774 | Mostly Cloudy | 48.3          |
| 8777 | Mainly Clear  | 48.3          |
| 8779 | Cloudy        | 48.3          |
| 8780 | Mostly Cloudy | 48.3          |
| 8781 | Clear         | 24.1          |

3027 rows × 2 columns

**data['Weather']=='Clear':** This part of the code creates a Boolean Series that checks whether each row in the 'Weather' column of the 'data' DataFrame is equal to the string 'Clear'. It results in a Series of True and False values, indicating which rows have 'Clear' as their weather condition.

**data['Visibility\_km']** > **40:** This part of the code creates another Boolean Series that checks whether each row in the 'Visibility\_km' column of the 'data' DataFrame has a value greater than 40. It results in a Series of True and False values, indicating which rows have a visibility greater than 40 kilometers.

(data['Weather']=='Clear') | (data['Visibility\_km']>40): This part of the code uses the | operator to combine the two Boolean Series created in steps 1 and 2 using a logical OR operation. This means that it will select rows where either the weather condition is 'Clear' or the visibility is greater than 40 kilometers.

['Weather', 'Visibility\_km']: This part of the code within square brackets specifies the columns you want to select from the DataFrame. In this case, you are interested in the 'Weather' and 'Visibility\_km' columns.

**data.loc[...]:** Finally, the .loc indexer is used to select rows and columns based on the conditions and column selections specified above. It will return a DataFrame containing only the rows where either the weather condition is 'Clear' or the visibility is greater than 40 kilometers, and it will include only the 'Weather' and 'Visibility\_km' columns for those selected rows.

So, the resulting DataFrame will contain only the rows where either the weather condition is 'Clear' or the visibility is greater than 40 kilometers, and it will show the values in the 'Weather' and 'Visibility\_km' columns for those rows.

|      | Weather       | Rel Hum_% | Visibility_km |
|------|---------------|-----------|---------------|
| 9    | Clear         | 35        | 48.3          |
| 17   | Mainly Clear  | 42        | 48.3          |
| 18   | Cloudy        | 42        | 48.3          |
| 19   | Clear         | 43        | 48.3          |
| 23   | Mainly Clear  | 45        | 48.3          |
|      |               |           | •••           |
| 8774 | Mostly Cloudy | 92        | 48.3          |
| 8777 | Mainly Clear  | 95        | 48.3          |
| 8779 | Cloudy        | 97        | 48.3          |
| 8780 | Mostly Cloudy | 98        | 48.3          |
| 8781 | Clear         | 99        | 24.1          |

(data['Weather']=='Clear'): This part of the code creates a Boolean Series that checks whether each row in the 'Weather' column of the 'data' DataFrame is equal to the string 'Clear'. It results in a Series of True and False values, indicating which rows have 'Clear' as their weather condition.

(data['Rel Hum\_%']>50): This part of the code creates another Boolean Series that checks whether each row in the 'Rel Hum\_%' column of the 'data' DataFrame has a value greater than 50. It results in a Series of True and False values, indicating which rows have relative humidity greater than 50%.

(data['Weather']=='Clear') & (data['Rel Hum\_%']>50): Here, the & operator is used to combine the Boolean Series created in steps 1 and 2 using a logical AND operation. This means that it will select rows where both the weather condition is 'Clear' and the relative humidity is greater than 50%.

(data['Visibility\_km']>40): This part of the code creates yet another Boolean Series that checks whether each row in the 'Visibility km' column of the 'data' DataFrame has a value

greater than 40 kilometers. It results in a Series of True and False values, indicating which rows have visibility greater than 40 kilometers.

## (data['Weather']=='Clear') & (data['Rel Hum\_%']>50) |

(data['Visibility\_km']>40): This part of the code combines the two sets of conditions using the | operator, which represents a logical OR operation. This means it will select rows where either both conditions (Clear weather and relative humidity > 50%) are met or the condition (Visibility > 40 km) is met.

['Weather', 'Rel Hum\_%', 'Visibility\_km']: This part of the code within square brackets specifies the columns you want to select from the DataFrame. In this case, you are interested in the 'Weather,' 'Rel Hum %,' and 'Visibility km' columns.

**data.loc[...]:** Finally, the .loc indexer is used to select rows and columns based on the combined conditions and column selections specified above. It will return a DataFrame containing rows where either the weather condition is 'Clear' and the relative humidity is greater than 50% or the visibility is greater than 40 kilometers. For these selected rows, it will show the values in the 'Weather,' 'Rel Hum %,' and 'Visibility km' columns.

So, the resulting DataFrame will contain rows that meet the combined conditions, and it will display the specified columns for those rows.
